Keywords

Keywords: Domino's Pizza, Descriptive Analytics, Data Visualization, Sales Analysis, Customer Preferences, Product Performance, Food-Delivery Analytics, Synthetic Dataset, Python, Pandas, Jupyter Notebook, Matplotlib, Data Cleaning, Sales Trend, Customer Ratings, Pizza Categories, Pizza Sizes, Flavour Preference, City-wise Sales, Online Sales, Dine-in Sales, Discounts, Refund Behaviour, Key Performance Indicators (KPIs), Business Insights, Predictive Analytics, Retail Analytics, Inventory Planning, Customer Segmentation.

Key Terms Used in the Report

- **Descriptive Analytics:** The process of organizing, summarizing and interpreting historical or observed data to understand what happened.
- **Data Visualization:** Representing numerical information through charts and graphs to make trends, comparisons and patterns easier to identify.
- **Product Performance:** A measure of how individual menu products perform using indicators such as units sold, revenue and customer ratings.
- **Customer Preference:** The observed tendency of customers toward particular products, sizes, flavours, categories, channels or price levels.
- **Synthetic Dataset:** Artificially generated transaction data designed to resemble realistic records for academic analysis.
- **Business Insight:** A practical interpretation of an analytical result that can support inventory, marketing, merchandising or customer-experience decisions.
- **KPI:** A key performance indicator that summarizes an important business measure.
- **Predictive Analytics:** A future analytical stage in which historical data are used to estimate future demand or customer behaviour.

Analytical Scope

The report focuses on quick-service pizza sales and customer behaviour. The analytical approach follows the sample report format by presenting the figure context, observation, business insight and measurable KPIs for each major topic, while replacing the original subject completely with Domino's pizza.

Note on Data

This report uses a synthetic Domino's pizza sales dataset created specifically for academic descriptive analytics. It is not a company-owned or officially published Domino's / Jubilant FoodWorks transaction database.

The dataset contains 150 transaction records representing a simulated 30-day period from 1 July 2026 to 30 July 2026. It includes product information, customer attributes, pricing, discounts, sales quantities, revenue, location, channel, payment method and refund status.

The dataset contains multiple simulated pizza products and Indian locations so that the project can demonstrate product-level, customer-level, regional and channel-level analysis. Because the records are synthetic, the resulting values should be used to demonstrate the analytical process rather than to make claims about actual company performance.

Dataset Variables

- Product_ID — Unique product identifier
- Product_Name — Pizza product name used for product ranking
- Category — Pizza category such as Classic, Cheesy, Spicy, BBQ, Veggie and Gourmet
- Size — Product size used for segmentation
- Price — Listed product price
- Discount — Discount percentage applied to the listed price
- Final_Price — Price after discount
- Units_Sold — Number of units represented by a transaction
- Revenue — Final_Price multiplied by Units_Sold
- Customer_Age — Simulated customer age
- Customer_Rating — Simulated rating from 1 to 5
- Purchase_Date — Date of simulated purchase
- City — Simulated market location
- Sales_Channel — Online or Dine-in/Takeaway
- Payment_Method — Payment mode
- Refund_Status — Refunded/cancelled or not

Objectives

The main purpose of this descriptive analytics project is to understand the simulated sales performance and customer preferences associated with Domino's pizza by exploring the questions below. The project converts raw transaction records into understandable charts, summary measures and business insights.

- Which Domino's products are the most purchased, and how does their sales performance compare?
- How does daily sales activity change across the 30-day simulated period, and which dates show the highest and lowest sales?
- What are the peak purchase hours, and when are customers most active?
- How does the popularity of Classic, Cheesy, Spicy, BBQ, Veggie and Gourmet pizza categories compare?
- What are the average customer ratings, and which categories are rated stronger or weaker?
- How do simulated pizza sales compare across major Indian cities and markets?
- How do Online and Dine-in/Takeaway sales compare in terms of channel contribution?
- How do customer age groups differ, and which segment contributes the greatest number of units?
- Which pizza sizes and flavours are most in demand for inventory planning?
- How do sales compare across discount ranges, without incorrectly claiming causation?
- What does refund/cancellation behaviour look like, and which categories require additional investigation?
- What KPIs can be calculated to summarize product, customer, regional and channel performance?
- How could the same descriptive framework support inventory, marketing and merchandising at real scale?
- What foundation can this project establish for future predictive analytics such as demand forecasting and refund prediction?

How This Would Work at Real Scale

At real scale, a pizza-delivery analytics system could combine authorized sales data from physical outlets and the online app with inventory, product, customer-service and refund information. The descriptive framework used in this project could then be updated daily or in near real time.

Area	How the Descriptive Framework Would Apply
Inventory Management	Monitor product, size and category demand to reduce stock-outs and excess ingredient inventory. Outlet-level and commissary-level availability can be compared with actual demand so replenishment can be prioritized.
Product Planning	Identify categories and pizza variants with consistently strong demand. New pizza launches can be compared with previous products using units, revenue, ratings and refund rates.
Regional Planning	Compare validated city and state demand to decide where new outlets or delivery hubs should be positioned. Local demand can be combined with category and size preferences to improve assortment planning.
Marketing & Promotions	Evaluate campaigns by comparing units, revenue and customer response before, during and after promotional periods. Discount effectiveness should be measured with profitability rather than volume alone.
Customer Experience	Combine ratings, reviews and refund/cancellation reasons to identify possible issues with taste, spice level, delivery time, packaging or order accuracy.
Online Sales	Use customer purchase and browsing behaviour to improve product recommendations, search ranking, product visibility and digital merchandising on the app.
Management Dashboards	Create dashboards showing KPIs such as revenue, units, average rating, refund rate, category contribution and channel performance so managers can monitor changes quickly.

Business Insight

A real-time analytics system would allow the business to move from simple historical reporting toward continuous decision support. High-demand pizzas could be replenished faster, weak-performing variants could be reviewed earlier, and regional or channel differences could be addressed before they become larger operational problems.

1. Most Purchased Domino's Products

Figure Description

The figure presents the ranking of Domino's products according to total simulated Units_Sold during the 30-day analysis period. The X-axis represents the individual products, while the Y-axis represents the total number of units sold. The bars allow direct comparison between the highest-demand products and products with comparatively lower sales. The visualization is useful for identifying products that may require greater inventory attention.

KPI

- Best-selling product: Margherita — 62 units
- Second-highest product: Farmhouse — 51 units
- Third-highest product: Peppy Paneer — 49 units
- Total simulated units sold: 460

Observation

The graph indicates that Margherita recorded the highest number of simulated units sold. Farmhouse and Peppy Paneer also showed strong demand, while the lower-ranked products generated comparatively fewer units. The difference between the leading products and the remaining products suggests that customer demand is not evenly distributed across the complete product range. This creates a clear product-performance hierarchy that can be used for further analysis.

Business Insight

High-performing products should receive priority in inventory replenishment, app visibility and store merchandising. Featured products can be supported with promotional campaigns when appropriate, while lower-performing products should be reviewed for price, flavour positioning, size availability, customer ratings and menu placement. In a real retail environment, product-level demand would also be combined with profit margin and stock availability

before making final decisions.

Additional Interpretation

Product rankings alone do not explain why a product performs well. A stronger analysis would combine product demand with price, discount, rating, refund rate, size availability and category.

2. Daily Sales Trend

Figure Description

The figure shows the Daily Sales Trend of simulated pizza units sold over the 30-day analysis period from 1 July 2026 to 30 July 2026. The X-axis represents the Purchase_Date and the Y-axis represents total Units_Sold for each day. Each point represents the aggregated units sold on that date, and the connected line shows how sales activity changed across the month. The chart helps identify sales peaks, lower-volume days and general fluctuations in daily demand.

KPI

- Average daily units sold: 15
- Highest-sales date: 2026-07-21 — 32 units
- Lowest-sales date: 2026-07-02 — 6 units

Observation

The graph shows noticeable fluctuations in daily sales rather than a perfectly constant pattern. The highest simulated activity occurred on 2026-07-21, while 2026-07-02 recorded a low value. Other peaks and dips appear across the month, indicating that daily purchase activity changes over time. In real retail data, such changes could be associated with weekends, promotions, product availability, salary cycles, holidays or other external factors.

Business Insight

Identifying high-sales days can help businesses prepare inventory and schedule marketing campaigns more effectively. Additional dough, cheese and topping stock can be positioned before expected high-demand periods, while promotional activity can be timed to increase traffic during strategically important dates. Daily monitoring can also help identify unusual drops that may indicate stock-outs, technical problems or weaker customer demand.

Additional Interpretation

The 30-day synthetic period demonstrates the analytical method but should not be interpreted as evidence of actual seasonal behaviour.

3. Peak Purchase Hours

Figure Description

The figure presents the distribution of simulated Units_Sold by Purchase_Hour. The X-axis represents the hour of purchase and the Y-axis represents total units sold during that hour. Comparing hourly activity makes it possible to identify the periods when customers are most active. This type of analysis is useful for online merchandising, promotional scheduling, kitchen staffing and delivery-fleet planning.

KPI

- Peak purchase hour: 21:00
- Units sold at peak hour: 68
- Lowest purchase hour: 10:00 — 3 units

Observation

The graph indicates that purchase activity varies by time of day. The highest simulated activity is concentrated around 21:00 (dinner time), with a smaller secondary rise around 13:00 (lunch time), while 10:00 records the lowest activity. The pattern suggests that customer purchasing behaviour is stronger during selected hours rather than being evenly distributed across the day.

Business Insight

Validated peak-hour information can help outlets schedule kitchen staff, delivery riders and customer-support resources when customers are most active. The app can highlight selected pizzas before peak periods, while order-processing teams can prepare for increased activity. Real store footfall and order data could similarly support staff scheduling.

Additional Interpretation

Peak-hour analysis is descriptive; it identifies when activity occurs but does not by itself explain the reason for that activity.

4. Pizza Category Popularity

Figure Description

The figure compares simulated units sold across major pizza categories including Classic, Cheesy, Spicy, BBQ, Veggie and Gourmet. The X-axis represents categories and the Y-axis represents total Units_Sold. The chart shows which categories contributed larger or smaller portions of total pizza demand during the simulated period.

KPI

- Best-selling category: Classic — 165 units
- Second-highest category: Cheesy — 120 units
- Total categories analysed: 6

Observation

Classic is the leading simulated pizza category, followed by Cheesy and other categories. The variation between categories indicates that customer demand differs according to category type. Categories with stronger sales contribute a larger share of total units and may represent higher customer interest within this synthetic dataset.

Business Insight

Popular categories should receive greater inventory attention and menu visibility. Lower-performing categories can be examined for pricing, topping intensity, availability and promotional effectiveness. Category-level decisions should also consider revenue and margin because a category with fewer units may still be commercially valuable if its average selling price or margin is higher.

Additional Interpretation

Category popularity is a descriptive measure and should be combined with profitability, refund rates and stock levels for real business decisions.

5. Customer Ratings

Figure Description

The figure presents the Average Customer Rating by pizza category. The X-axis represents the categories and the Y-axis represents average rating on a 1–5 scale. The purpose is to compare customer satisfaction across product groups and identify categories with relatively stronger or weaker ratings.

KPI

- Highest-rated category: Gourmet — 4.35/5
- Lowest-rated category: Spicy — 3.72/5
- Overall average rating: 4.09/5

Observation

The ratings show differences between pizza categories. Gourmet has the highest simulated average rating of 4.35, while Spicy has the lowest average at 3.72. The differences can help identify categories that appear to provide stronger customer satisfaction in the academic dataset.

Business Insight

Highly rated categories can be highlighted in product recommendations and menu merchandising. Categories with lower ratings should be investigated through review comments and refund reasons to identify possible concerns related to taste, spice level, freshness, packaging or delivery temperature. Improving product information may also help set customer expectations.

Additional Interpretation

Ratings in this project are synthetic and should not be presented as official Domino's customer-review statistics.

6. City-wise Sales

Figure Description

The figure compares simulated Units_Sold across the Indian cities represented in the dataset. The X-axis represents cities and the Y-axis represents total units sold. The chart is intended to show regional concentration of demand and identify markets that contribute comparatively larger or smaller sales volumes.

KPI

- Highest-sales city: Mumbai — 112 units
- Second-highest city: Delhi — 79 units
- Cities represented: 9

Observation

The graph indicates that Mumbai contributes the highest simulated sales volume, followed by Delhi and other cities. Other cities show comparatively smaller unit volumes. The variation suggests that customer demand is geographically uneven within the synthetic records.

Business Insight

High-performing cities could receive greater outlet density, ingredient stocking depth and targeted promotional campaigns when supported by real sales evidence. Category and size preferences can be analysed within each city to improve local menu assortment. Regional distribution planning can also reduce the risk of stock-outs in stronger markets.

Additional Interpretation

These results are synthetic and must not be interpreted as official Domino's city-wise or state-wise sales.

7. Online vs Dine-in/Takeaway Sales

Figure Description

The figure compares sales performance across the simulated Online and Dine-in/Takeaway channels. The analysis considers both Units_Sold and Revenue so that channel contribution is not judged only by transaction volume. Comparing channels helps identify where customers are purchasing and where additional merchandising or operational attention may be useful.

KPI

- Leading channel by units: Online — 268 units
- Dine-in/Takeaway revenue: Rs. 76,120.0
- Total channel revenue: Rs. 1,87,450.0

Observation

The channel comparison shows differences between Online and Dine-in/Takeaway activity. Online contributes the larger number of simulated units sold. The revenue comparison provides an additional view because a channel may sell fewer units but generate substantial revenue depending on sizes and prices.

Business Insight

Channel performance can guide marketing allocation, delivery-fleet sizing and customer-experience improvements. Strong online demand can justify stronger app merchandising and delivery-time optimisation, while dine-in demand can support in-store promotions and seating capacity planning. A unified inventory view can help avoid selling popular pizzas online while stores face shortages.

Additional Interpretation

Channel results may be affected by the synthetic sampling design and should be validated with actual sales and margin data.

8. Customer Age Preferences

Figure Description

The figure presents simulated pizza purchases across five customer age groups: Under 18, 18–24, 25–34, 35–44 and 45+. The X-axis represents the age group and the Y-axis represents total Units_Sold. Age segmentation provides a simple view of which customer segments contribute more purchase volume.

KPI

- Highest-volume age group: 18-24 — 142 units
- Lowest-volume age group: 45+ — 50 units
- Age groups analysed: 5

Observation

The age-group comparison shows that 18-24 contributes the highest simulated unit sales, followed closely by 25-34. Other groups contribute different levels of demand, indicating that purchase volume is not equally distributed across all age segments.

Business Insight

The strongest age segment can be used as a starting point for targeted campaigns, product recommendations and communication. However, businesses should avoid ignoring smaller segments; targeted offers and suitable size assortments can help improve engagement across customer groups.

Additional Interpretation

Age-group results are simulated and do not represent official Domino's customer demographics.

9. Pizza Size Preference

Figure Description

The figure presents total simulated Units_Sold by pizza size. The X-axis represents available sizes and the Y-axis represents the number of units sold. Size analysis is important for pizza delivery because assortment availability by size directly affects whether a customer can complete a purchase.

KPI

- Most demanded size: Medium (10") — 128 units
- Second-most demanded size: Large (12") — 102 units
- Sizes analysed: 6

Observation

The Medium (10") size records the highest simulated demand, while other sizes contribute different levels of sales. The chart highlights the relative demand distribution across the available sizes and can help identify sizes that require greater attention.

Business Insight

Popular sizes should be maintained at sufficient dough and packaging stock levels to reduce stock-outs. Real outlets can combine size demand with product, city and category to determine exactly where additional inventory is required. Solo-occasion small sizes and group-oriented large sizes may need different promotional strategies.

Additional Interpretation

Size demand should be measured over longer real periods and adjusted for product availability before being used for procurement.

10. Flavour Preference

Figure Description

The figure compares simulated pizza sales across the top individual products in the dataset. The X-axis represents the pizza and the Y-axis represents Units_Sold. The chart provides a simple view of flavour preference within the academic dataset.

KPI

- Most popular pizza: Margherita — 62 units
- Second-most popular pizza: Farmhouse — 51 units
- Pizzas analysed: top 6

Observation

Margherita is the most purchased simulated pizza, followed by Farmhouse. The difference in sales between products indicates that customers do not show equal demand for every flavour option.

Business Insight

Popular pizzas can receive greater inventory allocation and app visibility. Lower-demand pizzas can be stocked selectively or evaluated for regional or seasonal positioning. Flavour preferences can also be combined with size and category to identify high-demand product variants.

Additional Interpretation

Flavour popularity is synthetic and does not represent actual Domino's market preference.

11. Discount vs Sales

Figure Description

The figure compares observed sales across discount levels/ranges. The analysis is designed to determine whether higher-discount records are associated with different sales volumes. The chart should be interpreted carefully because many factors other than discount can influence sales, including product popularity, price, availability and customer demand.

KPI

- Average discount: 10.2%
- Highest discount observed: 30%
- Total simulated revenue: Rs. 1,87,450.0

Observation

Sales volume differs across discount ranges in the synthetic records. Some promotional levels show stronger observed unit sales, but this pattern alone cannot prove that discounting caused the additional sales. Product popularity and other factors may be influencing both variables.

Business Insight

Discount decisions should be evaluated using units sold, revenue and profit margin together. Outlets can use promotions strategically for selected pizzas, clearance ingredients or demand stimulation rather than applying high discounts universally. The objective should be profitable incremental demand, not simply higher unit volume.

Additional Interpretation

The relationship shown is descriptive association, not a causal experiment.

12. Refund / Cancellation Behaviour

Figure Description

The figure compares the percentage of simulated transactions marked as refunded or cancelled across pizza categories. The X-axis represents categories and the Y-axis represents the refund rate. Refund analysis is useful because high refund levels may indicate the need to investigate delivery delays, order accuracy, quality or spice-level expectation issues.

KPI

- Overall simulated refund rate: 3.2%
- Highest-refund category: Spicy — 9.8%
- Lowest-refund category: Classic — 0.0%

Observation

The overall simulated refund rate is 3.2%. Spicy has the highest category refund rate, while Classic and Veggie have the lowest. The difference indicates that refund behaviour varies by category within the synthetic records.

Business Insight

Categories with higher refunds should be investigated using cancellation reasons, delivery-time data and customer feedback. Better spice-level labelling, quality checks, packaging and delivery-time management may reduce avoidable refunds. Refund analysis can therefore support both customer experience and cost control.

Additional Interpretation

A higher refund rate does not automatically mean that a product is poor; the reason for the cancellation/refund must be examined.

Summary of Key Metrics

The following KPI table consolidates the main results of the synthetic dataset into a single management-style view. These metrics provide a quick summary while the preceding sections provide the detailed analytical explanation.

Objective	Key Metric	Result
Product performance	Best-selling product	Margherita
Product performance	Best-selling product units	62
Daily sales	Average daily units	15
Daily sales	Highest-sales date	2026-07-21
Peak hours	Peak purchase hour	21:00
Category	Best-selling category	Classic
Ratings	Highest-rated category	Gourmet (4.35/5)
Regional	Highest-sales city	Mumbai
Channel	Best channel by units	Online
Customer	Largest age group	18-24
Size	Most popular size	Medium (10")
Flavour	Most popular pizza	Margherita
Revenue	Total simulated revenue	Rs. 1,87,450.0
Sales volume	Total units sold	460
Customer experience	Overall average rating	4.09/5
Refunds	Overall refund rate	3.2%

KPI Interpretation

The KPI summary shows that product demand, customer satisfaction, geography, channel performance and refund behaviour can all be measured from transaction-level data. In a real retail environment, these measures could be placed on a dashboard and monitored regularly to identify changes in demand and support faster decisions.

Important Academic Limitation

Every value in this KPI table is calculated from the synthetic dataset. It must not be presented as official Domino's / Jubilant FoodWorks sales or customer statistics.

Next Steps: Descriptive → Predictive Analytics

The descriptive analysis performed in this project provides a foundation for future predictive analytics. Descriptive analytics answers questions such as what sold the most, which category was popular and which channel generated more units. Predictive analytics can then use historical patterns to estimate what may happen next.

Possible Predictive Applications

- Forecast future pizza sales by product, category and city using historical sales patterns.
- Predict demand for specific sizes and flavours to improve inventory planning.
- Identify products likely to become high-demand items before stock shortages occur.
- Predict customers who are likely to order again and support personalized offers.
- Estimate which orders have a higher probability of being cancelled or refunded.
- Optimize ingredient allocation across outlets, commissaries and delivery fulfilment zones.
- Recommend products based on previous orders, category preferences, sizes and flavours.
- Estimate expected sales under different promotional or discount scenarios.

Example Business Scenario

If real data repeatedly showed strong demand for Margherita in a particular city and size, a predictive model could estimate future demand for that product-size-city combination. Ingredient stock could then be positioned before demand occurs rather than only after stock begins to decline.

Business Insight

Moving from descriptive to predictive analytics can help a pizza-delivery business become more proactive. Instead of only reporting past sales, the business could forecast demand, anticipate refunds, personalize recommendations and optimize inventory. This could improve efficiency and reduce avoidable stock-outs and excess inventory.

Requirement for Real Implementation

Predictive models require larger, validated datasets, appropriate features, model evaluation and responsible handling of customer information. The current synthetic dataset is suitable for demonstrating descriptive analysis but is not sufficient to train a reliable production forecasting model.

Dataset Citation

Synthetic Domino's Pizza Sales Dataset (150 transaction records), generated for academic descriptive analytics purposes using simulated food-delivery sales, customer preferences, product attributes, Indian market locations and realistic retail-style variables.

Source-use Note

Official brand sources are used only for general brand/product context. All transaction-level sales, customer, revenue, rating, refund and KPI results in this report are generated from the synthetic academic dataset.

Appendix

Appendix A — Sample of Synthetic Dataset

Product_ID	Product_Name	Category	Size	Price	Discount	Units_Sold	Revenue	City	Channel
DM-P02	Peppy Paneer	Veggie	Medium (10")	399	20	3	957.6	Chandigarh	Dine-in/Takeaway
DM-P04	Chicken Dominator	BBQ	Regular (9")	349	15	2	593.3	Hyderabad	Online
DM-P01	Margherita	Classic	Large (12")	449	10	4	1616.4	Delhi	Online
DM-P06	Mexican Green Wave	Spicy	Medium (10")	399	5	2	758.1	Mumbai	Online
DM-P03	Farmhouse	Veggie	Personal (7")	199	0	3	597.0	Lucknow	Dine-in/Takeaway
DM-P05	Cheese Burst Supreme	Cheesy	Large (12")	549	0	5	2745.0	Chandigarh	Dine-in/Takeaway
DM-P07	Pepper Barbecue Chicken	BBQ	Regular (9")	349	0	3	1047.0	Pune	Online
DM-P08	Deluxe Veggie	Gourmet	Medium Combo	499	0	2	998.0	Delhi	Online

Appendix B — Python / Pandas Data Preparation

```
import pandas as pd
df = pd.read_csv('dominos_synthetic_150.csv')
df.drop_duplicates(inplace=True)
df['Purchase_Date'] = pd.to_datetime(df['Purchase_Date'])
df['Final_Price'] = df['Price'] * (1 - df['Discount']/100)
df['Revenue'] = df['Final_Price'] * df['Units_Sold']
df['Age_Group'] = pd.cut(df['Customer_Age'], [0,17,24,34,44,100], labels=['Under
18', '18-24', '25-34', '35-44', '45+'])
```

Appendix C — KPI Calculation Examples

```
Total Units = df['Units_Sold'].sum()
Total Revenue = df['Revenue'].sum()
Average Rating = df['Customer_Rating'].mean()
Best Product = df.groupby('Product_Name')['Units_Sold'].sum().idxmax()
Best Category = df.groupby('Category')['Units_Sold'].sum().idxmax()
Best City = df.groupby('City')['Units_Sold'].sum().idxmax()
Refund Rate = (df['Refund_Status'].eq('Yes').mean()) * 100
```

Appendix D — Visualization Examples

```
import matplotlib.pyplot as plt
product_sales = df.groupby('Product_Name')['Units_Sold'].sum().sort_values(ascending=False)
product_sales.head(8).plot(kind='bar')
plt.title("Top Domino's Products by Units Sold")
plt.xlabel('Product'); plt.ylabel('Units Sold'); plt.show()
```

Appendix E — Supporting Analysis Tables

Supporting tables can be generated from the same dataset using Pandas groupby operations for product, category, city, channel, age group, size, flavour, discount and refund status. These tables can be exported to Excel for further academic verification.

Appendix F — Academic Limitation

The dataset is synthetic and therefore cannot represent actual Domino's / Jubilant FoodWorks sales, customers, revenue, market share or official product performance. The purpose of the appendix is to make the analysis reproducible and demonstrate the use of Python, Pandas and Matplotlib in a descriptive analytics workflow.
